**Taxonomy, new species, Coleoptera, Dermestidae, *Attagenus*, Yemen**

**Abstract.** In the work presented here, a new species *Attagenus herrmanni* sp. nov. from Yemen is described, illustrated and compared with similar species. The new species belongs to the subfamily Attageninae, tribe Attagenini and differs from all the known species by the colours and setation of dorsal surfaces and structure of antennae and male genitalia.

**INTRODUCTION**

The family Dermestidae currently contains 1420 species and subspecies worldwide, 50 species being known from Arabian Peninsula (Háva 2003, 2007a,b, 2009, 2010, 2011, Zvantiev 2005). The present study is based on dermestid material deposited in collections specified below. The work contains results of my studies related to those published in my recently preceding articles.

**MATERIAL AND METHODS**

The size of the beetles or of their body parts can be useful in species recognition and thus, the following measurements were made:

total length (TL) - linear distance from anterior margin of pronotum to apex of elytra.

elytral width (EW) - maximum linear transverse distance.

Other abbreviations:

AHEC Private collection of Andreas Herrmann, Stade, Germany;

## DESCRIPTION

### *Attagenus herrmanni* sp. nov. (Figs 1-4)

**Type material.** Holotype (♂): „Jemen [Yemen], S-Jemen, Al Kawd, Lichtfalle, ix.2003, v. Harten“, (AHEC). Paratypes (6 ♂♂): the same data as with holotype but dates: vii-ix.2001, viii.2000, (3 AHEC, 2 JHAC). Type specimens were labelled with red, printed labels bearing the text as follows: “HOLOTYPE [or PARATYPE, respectively] *Attagenus herrmanni* sp. n. J. Háva det. 2012“.

**Description.** Male. Body (Fig. 1) measurements (mm): TL 2.60-2.75 EW 1.65-1.67; cuticle brown on dorsal surfaces, and brown on ventral surfaces; large and ovate. Head finely punctate with long, white pubescence. Palpi entirely brown; pubescence on mentum denser. Ocellus on front present. Antennae brown, 11-segmented, antennal club 3-segmented (Fig. 2). Pronotum finely punctate like head, covered by long, whitish-yellow pubescence, discally with two small, light-brown, distinct spots. Scutellum triangular, finely punctate as pronotum, with long white pubescence. Elytra finely punctate; cuticle brown, covered by whitish-yellow pubescence, with one transverse, median fasciae covered by brown pubescence and one brown spot in anterior part; anterior spot on each elytron not reaching suture (Fig. 1). Prosternal process broad and long, covered by long, white pubescence. Mesosternum and metasternum with long, white pubescence. Abdominal sternites with long, white pubescence (Fig. 4). Legs brown with whitish-yellow pubescence; tibiae with short, brown thorns. Male genitalia (Fig. 3).

Female unknown.

Figs 1-4. *Attagenus herrmanni* sp. nov.: 1-habitus; 2- antenna of male; 3- male genitalia; 4- abdomen.

**Differential diagnosis.** The new species is visually very similar to *Attagenus lynx* (Mulsant et Rey, 1868), but differs from it by the form of antennae and male genitalia and colour pattern of elytra.

**Distribution.** Yemen.

**Etymology.** Patronymic, the species is named in honour of my friend and colleague Andreas Herrmann (Stade, Germany).
